From Bayesian Inference to LLMs

Modern C++ Optimizations for Reverse-Mode Automatic Differentiation

STEVE BRONDER

Estimating COVID Infection Rates For Policy

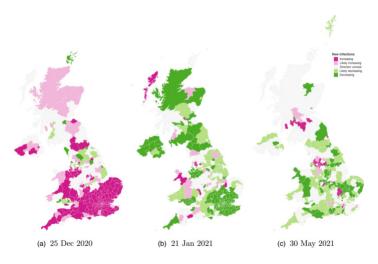

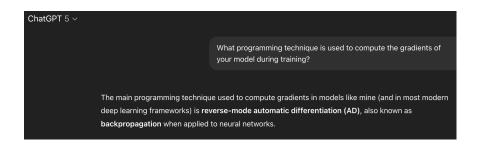

Figure: Probability of epidemic growth by local area

Automatic Differentiation Affects Your Day to Day

Computational technique for evaluating derivatives of functions expressed as computer programs by systematically applying the chain rule.

Ex: Newton's root finding method

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

find
$$f(x) = y$$
 where $y = 0$

$$f(x) = x^3 + x^2 + x (1)$$

$$f'(x) = 3x^2 + 2x + 1 \tag{2}$$

► Hamiltonian Monte Carlo:

► BFGS:

$$ightharpoonup s_k = -H_k \nabla_{\theta} f(\theta_k)$$

Stochastic Gradient Descent:

- Choices
 - ► Write by hand
 - finite difference,
 - symbolic differentiation
 - spectral differentiation
 - automatic differentiation

$$\begin{split} &\underbrace{\rho(\theta \mid \mathbf{y})}_{\text{posterior}} \propto \prod_{i=1}^{N} \left\{ \sum_{\mathbf{z}_i \in \left\{1,2,3\right\}} T_i \left[\underbrace{\prod_{t=2}^{T_i} \prod_{t=2}^{T_i} \prod_{\mathbf{z}_{i,t}-1, z_{i,t}} \prod_{t=1}^{T_i} \underbrace{\mathcal{N}\left(y_{i,t} \mid \eta_{i,t}, \sigma_{z_{i,t}}^2\right)}_{\text{state-dependent emission}} \right] \right\} \\ &\text{where} \quad \eta_{i,t} = \underbrace{\mathbf{x}_{i,t}^{\mathsf{T}} \beta}_{\text{fixed}} + \underbrace{\mathbf{z}_{i,t}^{\mathsf{G} \mathsf{T}} \mathbf{b}_{g[i]} + \mathbf{z}_{i,t}^{\mathsf{G} \mathsf{T}} \mathbf{c}_{c[i]} + u_{g[i]}}_{\text{crossed random effects}} + \underbrace{f(t_{i,t})}_{\text{state-specific offset} + \text{slope}} , \quad z_{i,t} \in \left\{1,2,3\right\}. \\ &\rho(\mathbf{f} \mid \boldsymbol{\psi}) = (2\pi)^{-T/2} \left| \mathbf{K} \right|^{-1/2} \exp\left(-\frac{1}{2} \mathbf{f}^{\mathsf{T}} \mathbf{K}^{-1} \mathbf{f}\right), \\ &\mathbf{K} = \sigma_i^2 \left(\mathbf{K}_{\mathsf{LP}}(\ell, \rho, \lambda) + \rho \, \mathbf{K}_{\mathsf{SE}}(\tilde{\ell})\right) + \sigma_n^2 \mathbf{I}, \quad \left[\mathbf{K}_{\mathsf{LP}}\right]_{tt'} = \exp\left(-\frac{(t-t')^2}{2\ell^2} - \frac{2 \sin^2\left(\pi \mid t-t' \mid / \rho\right)}{\lambda^2}\right), \\ &\mathbf{K}_{\mathsf{SE}} \right]_{tt'} = \exp\left(-\frac{(t-t')^2}{2\tilde{\ell}^2}\right), \quad \mathbf{K} = \mathbf{L}_{\mathsf{K}} \mathbf{L}_{\mathsf{K}}^{\mathsf{T}} \Rightarrow \log |\mathbf{K}| = 2 \sum_{i=1}^{T} \log\left((\mathbf{L}_{\mathsf{K}})_{jj}\right). \end{split}$$

Hierarchical mixed effects (non-centered, LKJ prior):

$$\begin{split} \mathbf{b}_{\mathbf{g}} &= \left(\mathbf{I}_{P_{G}} \otimes \operatorname{diag}(\boldsymbol{\tau}_{b}) \, \mathbf{L}_{R}\right) \, \tilde{\mathbf{b}}_{\mathbf{g}}, \quad \tilde{\mathbf{b}}_{\mathbf{g}} \sim \mathcal{N}(\mathbf{0}, \mathbf{I}), \quad \mathbf{c}_{c} = \operatorname{diag}(\boldsymbol{\tau}_{c}) \, \tilde{\mathbf{c}}_{c}, \quad \tilde{\mathbf{c}}_{c} \sim \mathcal{N}(\mathbf{0}, \mathbf{I}), \\ \operatorname{LKJ}_{P_{G}}(\boldsymbol{\eta}) \text{ prior on } \mathbf{R}, \quad \mathbf{L}_{R} \mathbf{L}_{R}^{\top} = \mathbf{R}, \quad \boldsymbol{\tau}_{b} \sim \prod_{j=1}^{P_{G}} \operatorname{Half-t}_{\boldsymbol{\nu}_{b}}(\boldsymbol{0}, s_{b}), \quad \boldsymbol{\tau}_{c} \sim \prod_{j=1}^{P_{C}} \operatorname{Half-t}_{\boldsymbol{\nu}_{c}}(\boldsymbol{0}, s_{c}), \\ u_{\mathbf{g}} \sim \mathcal{N}(\boldsymbol{0}, \sigma_{u}^{2}). \end{split}$$

- ► Faster than finite difference, more flexible than symbolic differentiation
- ► Allows for unknown length while and for loops
- Accurate to floating point precision
- Reverse Mode AD can compute partials derivatives of inputs at the same time

How Fast is AutoDiff?

Figure: AuToDiFf rUnS iN $\Theta(C(f))$ TiMe

Implementation Matters!

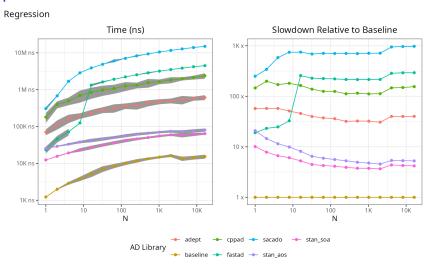

Figure: Benchmark for f' given $f(y) = N(y|X\theta, \sigma)$

Goal of this talk

- Explain how Reverse Mode Automatic Differentiation works
- Performance of high throughput memory intensive programs
- Show how modern C++ has led to cleaner and more efficient AD

► AD computes gradients of a program by applying the chain rule to its subexpressions.

$$f(x,y) = \log(x \cdot y)$$

$$f_1(x,y) = x \cdot y$$

$$f_2(u) = \log(u)$$

$$f(x,y) = f_2(f_1(x,y))$$

$$\frac{\partial f_1}{\partial x} = y$$

$$\frac{\partial f_1}{\partial y} = x$$

► AD computes gradients of a program by applying the chain rule to its subexpressions.

$$f(x,y) = \log(x \cdot y)$$

$$f_1(x,y) = x \cdot y \qquad \frac{\partial f_1}{\partial x} = y \qquad \frac{\partial f_1}{\partial y} = x$$

$$f_2(u) = \log(u) \qquad \frac{\partial f_2}{\partial u} = \frac{1}{u}$$

$$f(x,y) = f_2(f_1(x,y))$$

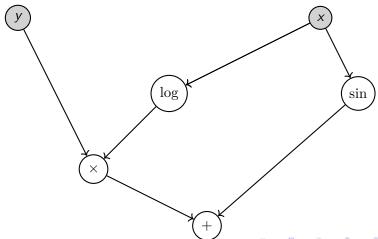

$$\frac{\partial f}{\partial x} = \frac{\partial f_2}{\partial f_1} \cdot \frac{\partial f_1}{\partial x} = \frac{1}{f_1(x,y)} \cdot y = \frac{y}{x \cdot y} = \frac{1}{x},$$

$$\frac{\partial f}{\partial y} = \frac{\partial f_2}{\partial f_1} \cdot \frac{\partial f_1}{\partial y} = \frac{1}{f_1(x,y)} \cdot x = \frac{x}{x \cdot y} = \frac{1}{y}.$$

Data Tye: Expression Graph

Goal: Calculate the full gradient by accumulating partial gradients (adjoints) through the a graph of subexpressions.

$$z = \log(x) \cdot y + \sin(x)$$

What is Automatic Differentiation

For Reverse Mode AD, each node performs two functions.

► Forward Pass:

$$\mathit{v}_2 = \mathit{f}(\mathit{v}_0,\mathit{v}_1)$$

What is Automatic Differentiation

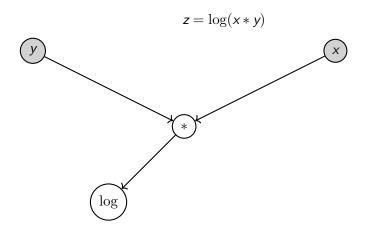

For Reverse Mode AD, each node performs two functions.

► Forward Pass:

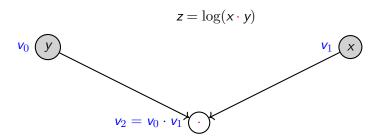

$$v_2 = f(v_0, v_1)$$

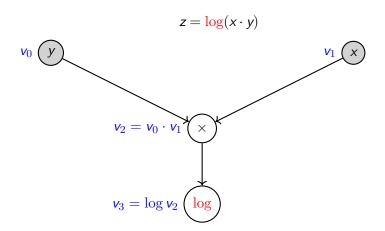

Reverse Pass: Given v_2 's adjoint (partial gradient) $\overline{v_2}$ Calculate the local adjoint-Jacobian update for v_0 and v_1 .

$$\mathit{chain}(\overline{v_2}, v_0, v_1) = \left\{ \overline{v_0} \mathrel{+}= \frac{\partial v_2}{\partial v_0} \overline{v_2}, \overline{v_1} \mathrel{+}= \frac{\partial v_2}{\partial v_1} \overline{v_2} \right\}$$

$$z = \log(x \cdot y)$$

How do we calculate the adjoint Jacobian?

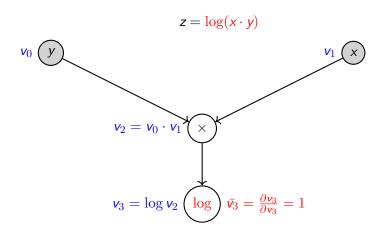

Let \overline{v}_i be the adjoint of v_i

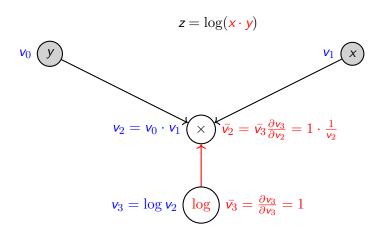

$$\overline{\mathbf{v}}_i = \frac{\partial \mathbf{v}_{i+1}}{\partial \mathbf{v}_i} \overline{\mathbf{v}}_{i+1}$$

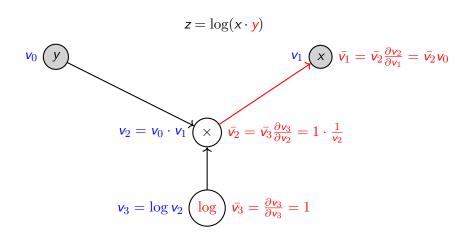

Automatic Differentiation only needs the partials of the intermediates

$$v_2 = v_0 \cdot v_1 \qquad \frac{\partial v_2}{\partial v_0} = v_1, \frac{\partial v_2}{\partial v_1} = v_0$$

$$v_3 = \log(v_2) \qquad \frac{\partial v_3}{\partial v_2} = \frac{1}{v_2}$$

$$z = \log(x \cdot y)$$

$$v_0 \quad y \quad \bar{v_0} = \bar{v_2} \frac{\partial v_2}{\partial v_0} = \frac{1}{v_2} v_1 \qquad v_1 \quad \bar{v_1} = \bar{v_2} \frac{\partial v_2}{\partial v_1} = \frac{1}{v_2} v_0$$

$$v_2 = v_0 \cdot v_1 \quad \times \quad \bar{v_2} = \bar{v_3} \frac{\partial v_3}{\partial v_2} = 1 \cdot \frac{1}{v_2}$$

$$v_3 = \log v_2 \quad \log \bar{v_3} = \frac{\partial v_3}{\partial v_3} = 1$$

$$z = \log(x \cdot y)$$

$$v_0 \quad y \quad \bar{v_0} = \bar{v_2} \frac{\partial v_2}{\partial v_0} = \frac{1}{v_2} v_1 = \frac{1}{y} \qquad v_1 \quad \bar{v_1} = \bar{v_2} \frac{\partial v_2}{\partial v_1} = \frac{1}{v_2} v_0 = \frac{1}{x}$$

$$v_2 = v_0 \cdot v_1 \quad \times \quad \bar{v_2} = \bar{v_3} \frac{\partial v_3}{\partial v_2} = 1 \cdot \frac{1}{v_2}$$

$$v_3 = \log v_2 \quad \log \quad \bar{v_3} = \frac{\partial v_3}{\partial v_3} = 1$$

What Do AD Libraries Care About?

- Flexibility:
 - Debugging, exceptions, conditional loops, matrix subset assignment
- : Efficiency:
 - ► Efficiently using a single CPU/GPU
- Scaling
 - Efficiently using clusters with multi-gpu/cpu nodes

How do we keep track of our reverse pass?

- Source code transformation
 - Unroll all forward passes and reverse passes into one function

Good: Fast

Bad: Hard to implement, very restrictive

How do we keep track of our reverse pass?

- Source code transformation
 - Unroll all forward passes and reverse passes into one function

Good: Fast

Bad: Hard to implement, very restrictive

- Operator Overloading
 - Nodes in the expression graph are objects which store a forward and reverse pass function

Good: Easier to implement, more flexible

Bad: Less optimization opportunities

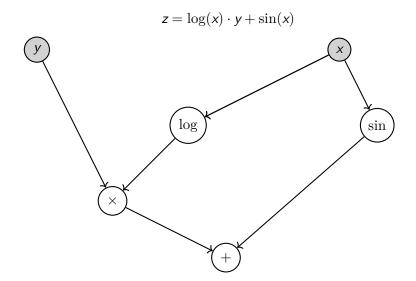

Newer AD packages use a combination of both

How do we keep track of our reverse pass?

Static (Fast) vs. Dynamic (Flexible) graphs

- ► Known expression graph size at compile time? (Static)
- Reassignment of variables (Dynamic easy, Static hard)
- ► How much time do I have? (Dynamic)

Make A Tape

Tape of Expression Graph

$$f(x, y) = \log(x)y + \sin(x)$$

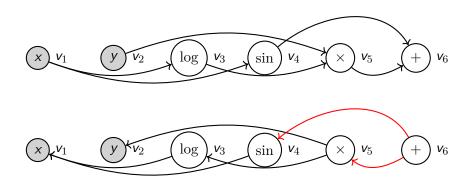

Figure: Topological sort of expression graph

Operator Overloading Approach

The operator overloading approach usually involves:

- Tracking the expression graph of reverse pass function calls
- A pair scalar type to hold the value and adjoint

Allows conditional loops and reassignment of values in matrices Nodes of expression graph can be collapsed Example Godbolt

Operator Overloading: Simple

```
struct var impl {
 double val ;
 double adj ;
 virtual void chain() {}
 var_impl(double val) : val_(val), adj_(0.0) {}
static std::vector<std::shared_ptr<var_impl>>> tape;
struct var {
  std::shared ptr<var impl> vi ;
  var(std::shared_ptr<var_impl>& vi) : vi_(vi) {
    tape.push back(vi);
```

Operator Overloading: Simple

```
struct mul_vv final : public var_impl {
 var op1;
 var op2;
 mul vv(double val, var op1, var op2):
     var_impl(val), op1_(op1), op2_(op2) {}
 void chain() {
   op1 .adj() += op2 .val() * this->adjoint;
   op2 .adj() += op1 .val() * this->adjoint_;
operator*(var x, var y) {
  return var{
   std::make shared<mul vv>(
      x.val() * v.val(), x, y);
```

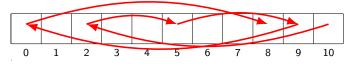

Operator Overloading: Simple

```
void grad(var& v) {
  v.adj() = 1.0;
  for (auto& x : tape | std::views::reverse) {
   x->chain();
var x(2.0);
var y(4.0);
auto z = x;
while (value(z) < 10) {</pre>
  z += x * log(y) + log(x * y) * y;
grad(z);
```

Full Example

Issues

Noncontiguous Access Pattern

Issues

Contiguous Access Pattern

```
struct Tape {
 monotonic buffer resource mbr{1<<16};
  polymorphic_allocator<std::byte> pa{&mbr};
  std::vector<var impl*> tape;
  void clear() {
   tape.clear();
   mbr.release();
  template <typename T, typename Types>
  auto* add(Types& ... args) {
    return g_ad.tape.emplace back(
      g_ad.pa.new_object<T>(args ... ));
static Tape g_ad{};
```

```
struct var_impl {
   double val;
   double adj;
   virtual void chain() {};
}; // 24 bytes
struct var {
   var_impl* vi_;
   var(double val):
     vi_(g_ad.template add<var_impl>(val)) {}
}; // 8 bytes
```

```
struct mul_vv : public var impl {
 var op1_;
 var op2;
 void chain() {
   op1_->adjoint_ += this->adjoint_ * op2_->value_;
   op2_->adjoint_ += this->adjoint_ * op1_->value_;
}; // 40 bytes
operator*(var op1, var op2) {
  return var{g_ad.template add<mul_vv>(
    op1.val() * op2.val(), op1, op2)};
```

```
void compute grads(var x, var y) {
 var z = -10:
 while (z.val() < 20) {
    z += log(x * y);
 grad(z):
// Later in program
for (int i = 0; i < 1e10; ++i) {
 var x = compute x(...);
 var y = compute y(...);
 compute_grads(x, y);
  do something with grads(x.adj(), y.adj());
  tape.clear();
 mbr.release();
```

So Many Operator Classes

```
struct mul vv;
struct mul vd;
struct mul dv;
struct add_vv;
struct add_dv;
struct add vd;
struct subtract_vv;
struct subtract dv;
struct subtract vd;
struct divide_vv;
struct divide dv;
struct divide_vd;
```

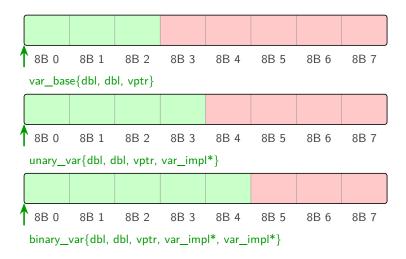

Reduce Boilerplate

```
template <typename F>
struct callback var impl : public var impl {
  F rev functor:
 template <std::floating_point S>
 explicit callback var impl(S&& value,
    F&& rev functor)
    : var impl(value).
      rev functor (rev functor) {}
 void chain() final { rev functor (*this); }
}; // 24 + 8B * N
// Helper for callback var impl
template <std::floating_point FwdVal, typename F>
auto lambda var(FwdVal val, F&& rev functor) {
  return var(
    new_var_impl<callback_var_impl<F>>(
     val.
      std::forward<F>(rev functor)));
```

Reduce Boilerplate

```
template <typename T1, typename T2>
requires any var<T1, T2>
inline auto operator*(T1 op1, T2 op2) {
  return lambda_var(value(op1) * value(op2),
    [op1, op2](auto&& ret) mutable {
      if constexpr (is_var_v<T1>) {
        adjoint(op1) += adjoint(ret) * value(op2);
      if constexpr (is var v<T2>) {
        adjoint(op2) += adjoint(ret) * value(op1);
    });
```

Poor Cache Use

```
double z = log(x * y);
```

Break it down

```
double v0 = x;
double v1 = y;
double v2 = x * y;
double v3 = log(v2)
double bar_v3 = 1;
double bar_v2 = bar_v3 * 1/v2;
double bar_v1 = bar_v2 * v0;
double bar_v0 = bar_v2 * v1;
```

Code like the following very hard / impossible in source code transform

```
while(error < tolerance) {
    // ...
}</pre>
```

```
struct var {
    double values_;
    double adjoints_;
    var(double x) : values_(x), adjoints_(0) {}
};
```

```
template <typename F, typename... Exprs>
struct expr {
  var ret_;
  std::tuple<deduce_ownership_t<Exprs>...> exprs_;
  std::decay_t<F> f_;
  template <typename FF, typename... Args>
  expr(double x, FF&& f, Args&&... args):
    ret_(x), f_(std::forward<F>(f)),
    exprs_(std::forward<Args>(args)...) {}
};
```

```
template <typename T1, typename T2>
requires any_var_or_expr<T1, T2>
inline auto operator*(T188 lhs, T288 rhs) {
  return make expr(value(lhs) * value(rhs),
  [](auto&& ret, auto&& lhs, auto&& rhs) {
    if constexpr (!std::is arithmetic v<T1>) {
      adjoint(lhs) += adjoint(ret) * value(rhs);
    if constexpr (!std::is arithmetic v<T2>) {
      adjoint(rhs) += adjoint(ret) * value(lhs);
  }, std::forward<T1>(lhs), std::forwar<u>d<T2>(rhs));</u>
```

```
template <typename Expr>
inline void grad(Expr& z) {
   adjoint(z) = 1.0;
   auto nodes = collect_bfs(z);
   eval_breadthwise(nodes);
}
```

```
auto z = x * log(y) + log(x * y) * y;
expr<Lambda<Plus>,
    expr<Lambda<Mult>, var, expr<Lambda<Log>, var>>,
    expr<Lambda<Mult>,
    expr<Lambda<Log>, expr<Lambda<Mult>, var, var>>,
```

Comparison

Table:
$$f(x, y) = x \log(y) + \log(xy)y$$
;

Method	CPU Time	% Improvement
Shared Ptr	508ns	1.0
MonoBuff	121ns	3.9x
Lambda	112ns	4.2x
Source Code Transform	26.5ns	19×
Baseline	2.82ns	180×

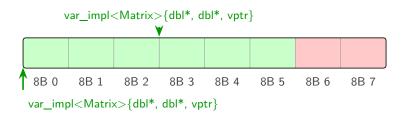

```
Matrix<var> B(M, M);
Matrix<var> X(M, M);
Matrix<var> Z = X * B.transpose();
```

```
template <typename MatrixType>
struct arena_matrix :
   public Eigen::Map<MatrixType> {
   using Base = Eigen::Map<MatrixType>
   template <typename T>
   arena_matrix(T&& mat) :
   Base(copy_to_arena(mat.data(), mat.size()),
        mat.rows(), mat.cols()) {}
};
```

```
// Array of Structs
struct Matrix<var> {
   var* data_;
};
// Struct of Arrays
struct var_impl<Matrix<double>>> {
   arena_matrix<double> value_;
   arena_matrix<double> adjoint_;
   virtual void chain() {}
};
```

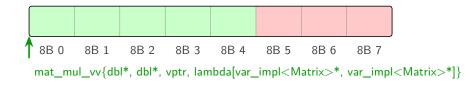

- Array of Structs Matrix<var>:
 - ► Simple, most algorithms Just WorkTM
 - Adds a lot to expression graph
 - turns off SIMD

- Array of Structs Matrix<var>
 - ► Simple, most algorithms Just Work™
 - Adds a lot to expression graph
 - turns off SIMD
- Struct of Arrays var<Matrix>:
 - ► Hard, everything written out manually
 - Collapses matrix expressions in tree
 - SIMD can be used on values and adjoints

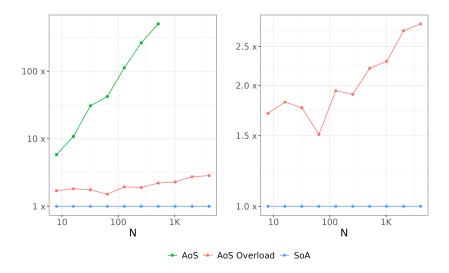

Matrix Multiplication Example

```
template <typename T1, typename T2>
requires any var<T1, T2>
inline auto operator*(T186 op1, T286 op2) {
  return lambda_var(value(op1) * value(op2),
    [op1, op2](auto₩ ret) mutable {
      if constexpr (is_var_matrix_v<T1>) {
        adjoint(op1) += adjoint(ret) *
            value(op2).transpose();
      if constexpr (is var matrix v<T2>) {
        adjoint(op2) += value(op1) * adjoint(ret);
    });
```

Matrix Multiplication Benchmark

Scaling Up: CPU
